PRESSURE CALIBRATION

Description

The pressure calibration was done in the Measurement Standards Laboratory (MSL) of Vaisala Oyj on May 23, 2008 by Ville Vuorio.
Before measurements the transmitter was allowed to stabilize to the conditions of the laboratory for at least 2 hours with + 15,0 VDC ± 0,3 VDC power supply switched on.
Before the calibration the Multi Point Correction (MPC) and Linear Correction (LC) -values for the transmitter were read from the transmitter's memory.
The pressure readings of the transmitter were compared to the values of the reference pressure transmitter in the range from 500 to 1100 hPa absolute pressure.
Pressure readings of the transmitter were read with the MPC -corrections ON and the LC -corrections OFF. The pressure reading P was then calculated using the old LC -corrections. New LC -corrections were calculated using the least squares method, input into the memory of the transmitter and the final results were calculated using these new corrections.
The pressure calibration is valid only with the LC corrections switched ON.
Pressure values were read via serial port with resolution of 0,01 hPa.
The used pressure transmitting medium was air and/or nitrogen.

Reference

DHI PPC3 Pressure Controller/Calibrator, serial number 722, traceable to the National Institute of Standards and Technology (NIST. USA) via MSL and Centre for Metrology and Accreditation (MIKES).

Uncertainty

The reported expanded uncertainty of measurement is stated as the standard uncertainty of measurement multiplied by the coverage factor k = 2, which for a normal distribution corresponds to a coverage probability of approximately 95 %. The standard uncertainty of measurement has been determined in accordance with EA Publication EA-4/02.

- The uncertainty is calculated from the uncertainties caused from the reference equipment, calibration process and unit under calibration (UUC) including resolution, stability (short term), linearity, repeatability, hysteresis and rounding of the final results.
- The measurement results and uncertainty may be interpolated between measurement points.

The measurement uncertainty represents the situation at the time and conditions of calibration. When using the UUC at different conditions and at different time the effect of the conditions and stability of the UUC shall be evaluated separately.

TEMPERATURE CALIBRATION

Description

The temperature calibration was done in the Measurement Standards Laboratory (MSL) of Vaisala Oyj on May 22, 2008 by Antti Leivonen.
Before measurements the transmitter was allowed to stabilize to the conditions of the laboratory for at least 2 hours with + 15,0 VDC ± 0,3 VDC power supply switched on.
The temperature readings of the transmitter were compared to the values of the reference thermometer at 23,0 °C in a stirred liquid calibration bath.
The probes were protected with a plastic cover before immersing to the bath liquid.
Temperature values were read via serial port with resolution of 0,01 °C.
New correction coefficients were calculated and input into the transmitter's memory.
Temperature values are given according to the International Temperature Scale of 1990, ITS-90.

Calculations

New offset- and gain coefficients were calculated from the measurement results. The coefficients are presented in table 7. The final results were calculated using equations 1 and 2.

T = T offset + T gain · T', where (1)
T' = Reading without offset- and gain corrections [°C]

Ta = Ta offset + Ta gain · Ta', where (2)
Ta' = Reading without offset- and gain corrections [°C]

New coefficients were input into the transmitter's memory.

Table 7. Coefficients

	Old coefficients	New coefficients	
T offset	0,000000000000	0,014419999100	[°C]
T gain	1,000000000000	1,000000000000	
Ta offset	0,000000000000	0,010010000500	[°C]
Ta gain	1,000000000000	1,000000000000	

Final temperature results

The reference and the reading values are averages of ten independent observations. The standard deviations are included in the calculated uncertainties.

Table 8. Final temperature results, T

HUMIDITY CALIBRATION

Description

The humidity calibration was done in the Measurement Standards Laboratory (MSL) of Vaisala Oyj on May 23, 2008 by Antti Leivonen.
Before measurements the transmitter was allowed to stabilize to the conditions of the laboratory for at least 12 hours with + 15,0 VDC ± 0,3 VDC power supply switched on.
The humidity readings of the transmitter were compared to the reference humidity values at room temperature in Salt Solution Generator in the range from 0 to 97 %RH.
The humidity readings were read via serial port with resolution of 0,01 %RH.
Coefficients RHl_0, RHl_1, RHl_2, RHl_3 and RHl_4 were calculated from the observed humidity values and input to the transmitter's memory.
Measurements were made in Salt Solution Generator, where the temperature was + 23,08 °C ± 0,03 °C. The 0,1 %RH value was measured in dry nitrogen flow which temperature was + 22,77 °C ± 0,13 °C.

References

Salt Solution Generator UG 8195, traceability is based on the physical phenomenon in which the equilibrium relative humidity values associated with certain saturated salt solutions are known.
The operation principle and values of the Salt Solution Generator are based on Lewis Greenspan's research /1/ and on the international standard ASTM E 104 - 85 /2/.

Uncertainty

The reported expanded uncertainty of measurement is stated as the standard uncertainty of measurement multiplied by the coverage factor k = 2, which for a normal distribution corresponds to a coverage probability of approximately 95 %. The standard uncertainty of measurement has been determined in accordance with EA Publication EA-4/02.

- The uncertainty is calculated from the uncertainties caused from the reference equipment, calibration process and unit under calibration (UUC) including resolution, stability (short term), linearity, repeatability, hysteresis and rounding of the final results.
- The measurement results and uncertainty may be interpolated between measurement points.

The measurement uncertainty represents the situation at the time and conditions of calibration. When using the UUC at different conditions and at different time the effect of the conditions and stability of the UUC shall be evaluated separately.

Calculations

The calibration was made using the coefficients presented in table 10.
using the least squares method and input into the transmitter's memory.
Complete description of calculations performed is available in the Measurement Standards Laboratory.
During the measurement only temperature T was recorded and the Ta value was calculated using temperature measurement results. With this method the exact humidity readings were calculated with old and new coefficients using equation 3.

$RH_{OUT} = RH \cdot P_{ws} / P_{wa}$, where (3)

RH = Humidity reading with offset- and gain corrections [%RH]

$$P_{ws} = 6{,}1078 \cdot 10^{7{,}5\left(\frac{T}{T+237{,}3}\right)} \quad (4)$$

$$P_{wa} = 6{,}1078 \cdot 10^{7{,}5\left(\frac{Ta}{Ta+237{,}3}\right)} \quad (5)$$

Measurement results

The measurements were made for ascending and descending humidity values. The probe was allowed to stabilize to each humidity for 10 minutes before the reference values were recorded and the humidity and temperature values were recorded ten times. The humidity values were then calculated using the equation 3 and coefficients given in table 10. The calculated humidity values in table 11 are averages of these values.
